Overview

- Contemporary approaches to cognition
- The division between psychometric and experimental approaches
- A call for a symbiotic approach
- Appreciating the true complexity of explanatory constructs
 - The need for more elaborate theoretical models
 - The need for models of theoretical development

Overview

- Contemporary approaches to cognition

Saito & Towse (2007): Extent of citation popularity of the working memory

concept

What types of theoretical debates are there?

- At the most general level, we can contrast two candidate frameworks for thinking about working memory:
 - A Piagetian concern with explaining developmental change and cognitive stability through just a few global parameters
 - A Broadbent-like information processing model that attempts to map out the architecture of cognition

What types of theoretical debates are there?

Piaget

- Macro-level
- Generic concepts
- Resonances with psychometric analyses
- Almost defined what it means to have a developmental theory

Broadbent

- Micro-level
- Identifies functional properties
- Convenient for experimental decomposition
- Helped to shape a “revolution” in cognitive science

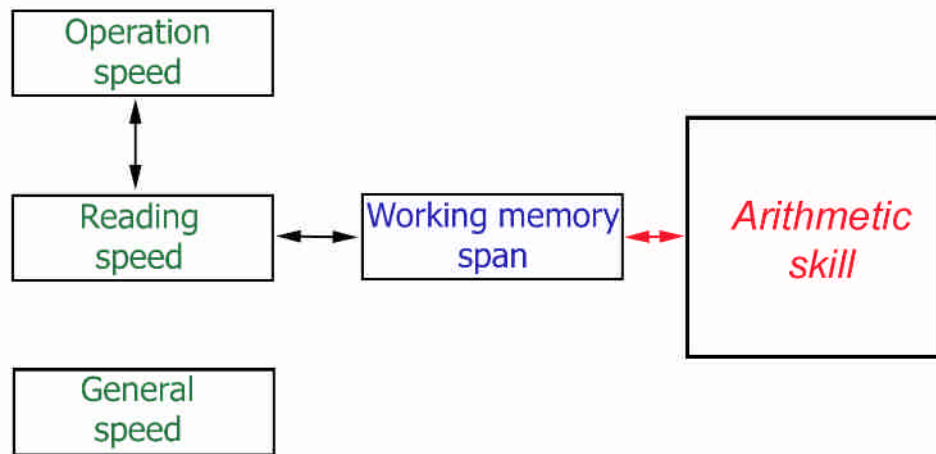

Macro-level variables underlying working memory capacity

- Processing speed
 - Links to changes with aging (Salthouse, 1992)
 - Lifespan changes in developmental cascade (Hale, Myerson & Lawrence, 2007)
 - Processing speed as an index of resource demand (Case, 1985)

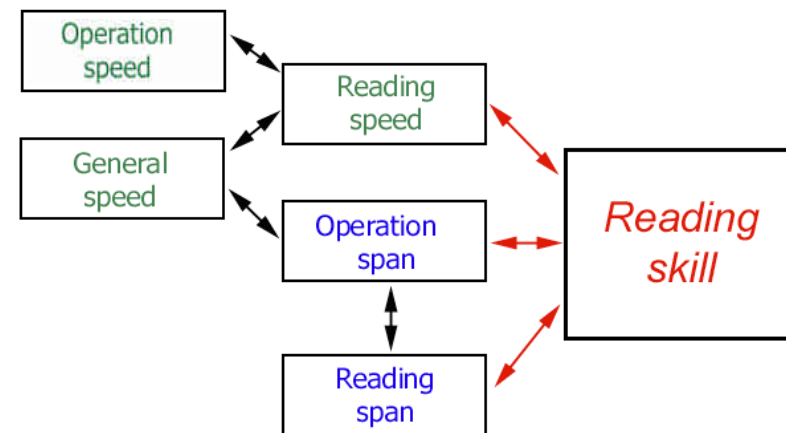

Unpacking processing speed as a construct

Predictions of scholastic skill

(data from Hitch, Towse & Hutton, 2001)

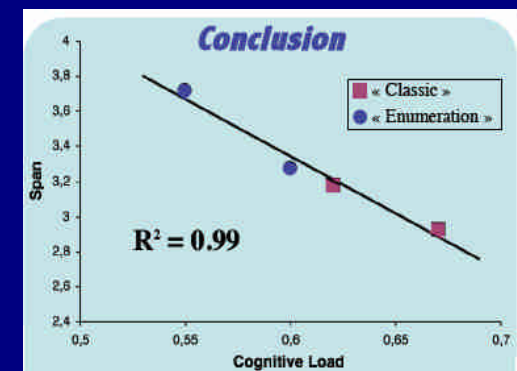

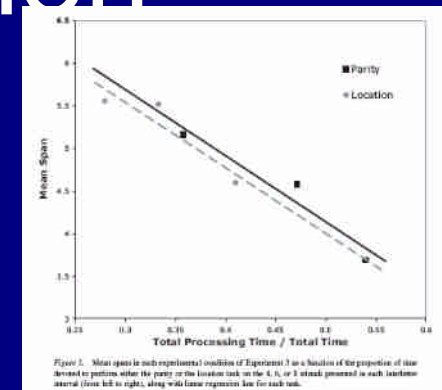

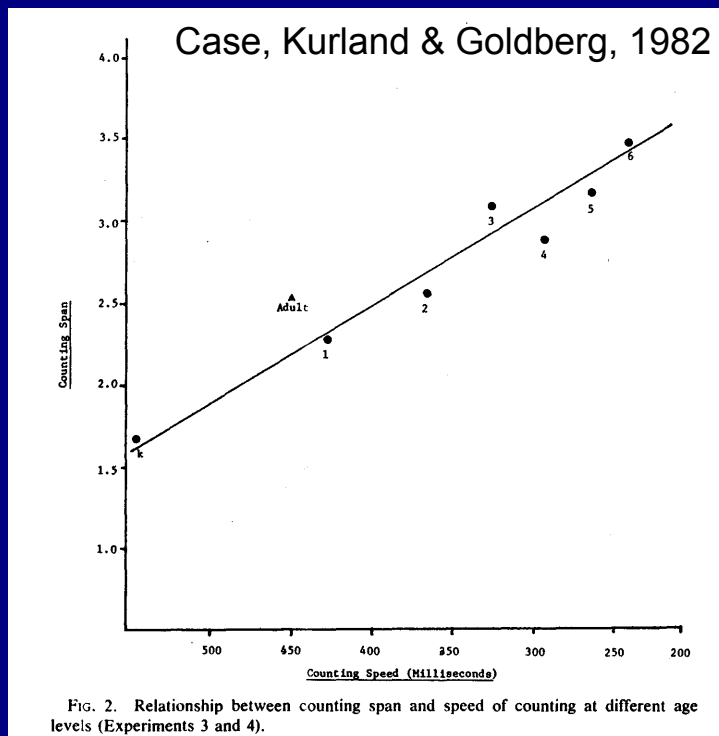

Hitch, G.J., Towse, J.N., & Hutton, U. "What Limits children's working memory span? Theoretical accounts and application for scholastic development." *Journal of Experimental Psychology*

Hitch, G.J., Towse, J.N., & Hutton, U. "What Limits children's working memory span? Theoretical accounts and application for scholastic development." *Journal of Experimental Psychology*

Unpacking processing speed as a construct

The single slope assumption

Reading span data

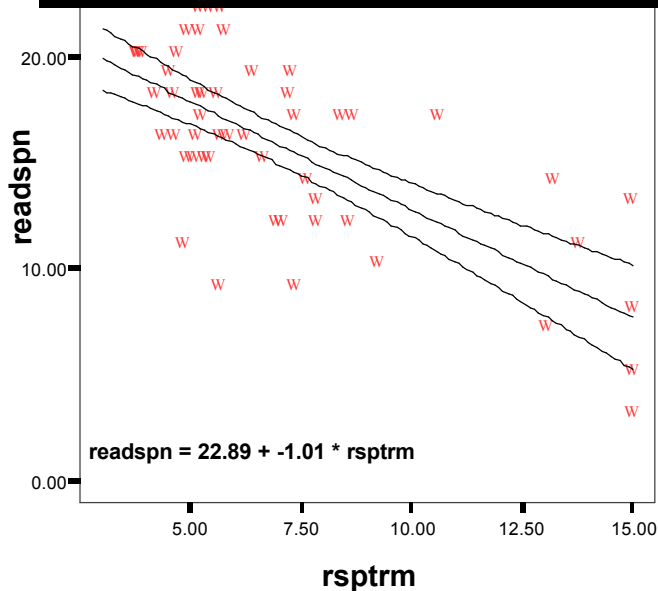

Towse, Hitch, Horton & Harvey (in prep)

- Two forms of reading span data differing only in whether recall items were part of the processing sentences
- Speed: span correlation overall: $r(105)=-.540$, $p<.001$, still sig after partialling out age

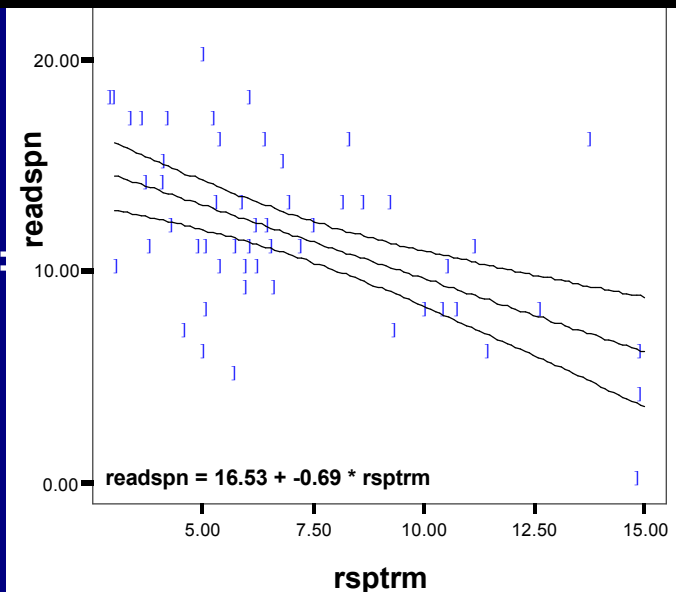

Words from sentence $r(52)=-.734$

Words unrelated to sentence $r(48)=-.480$

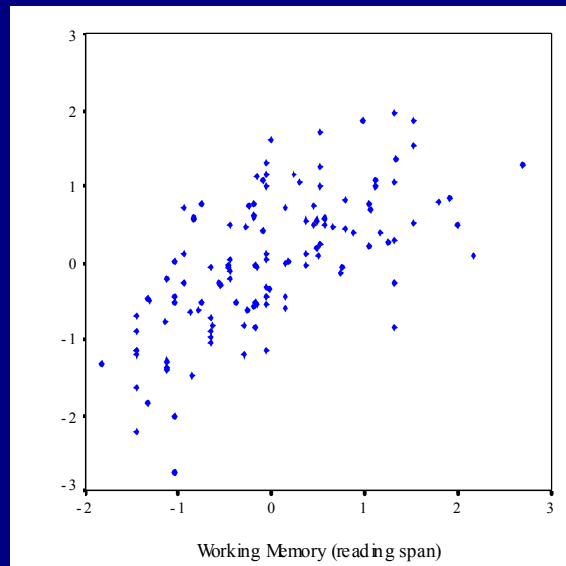

Chow test for equality of slopes: $F(1,104)=7.63$, $p=.007$

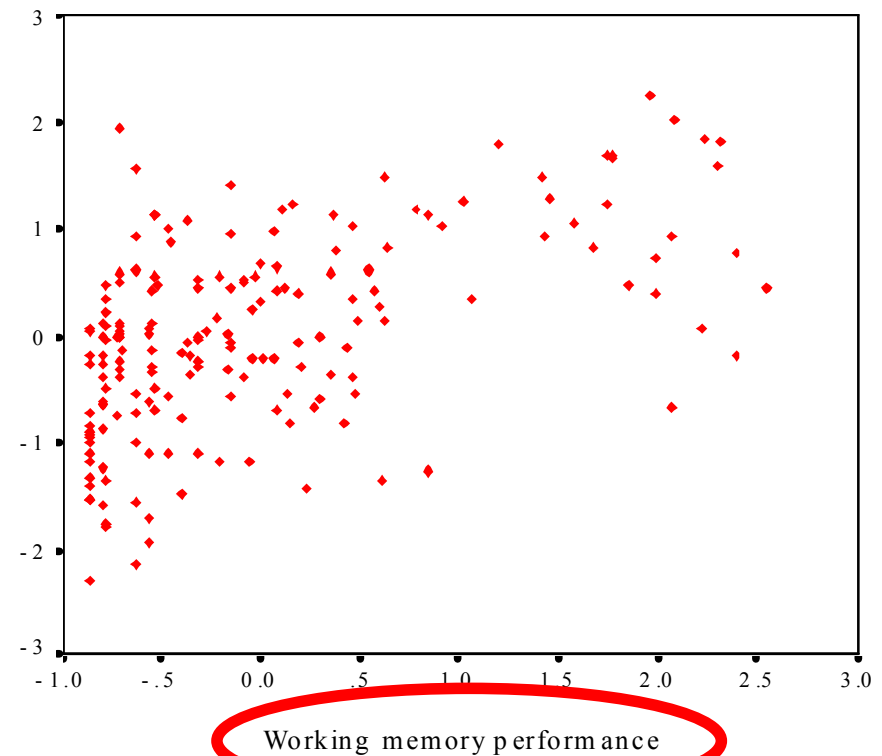

These correlations
length, $z=2.08$, $p<.05$

The predictive prowess of working memory: Business as usual?

N=182, primary school children: Towse, Hitch et al. (unpub))

Working memory is not just about how much gets remembered,
but also how persistent or long-lasting 'memory traces' are

An alternative to the emphasis on size -Working Memory period

Potential utility of working memory period

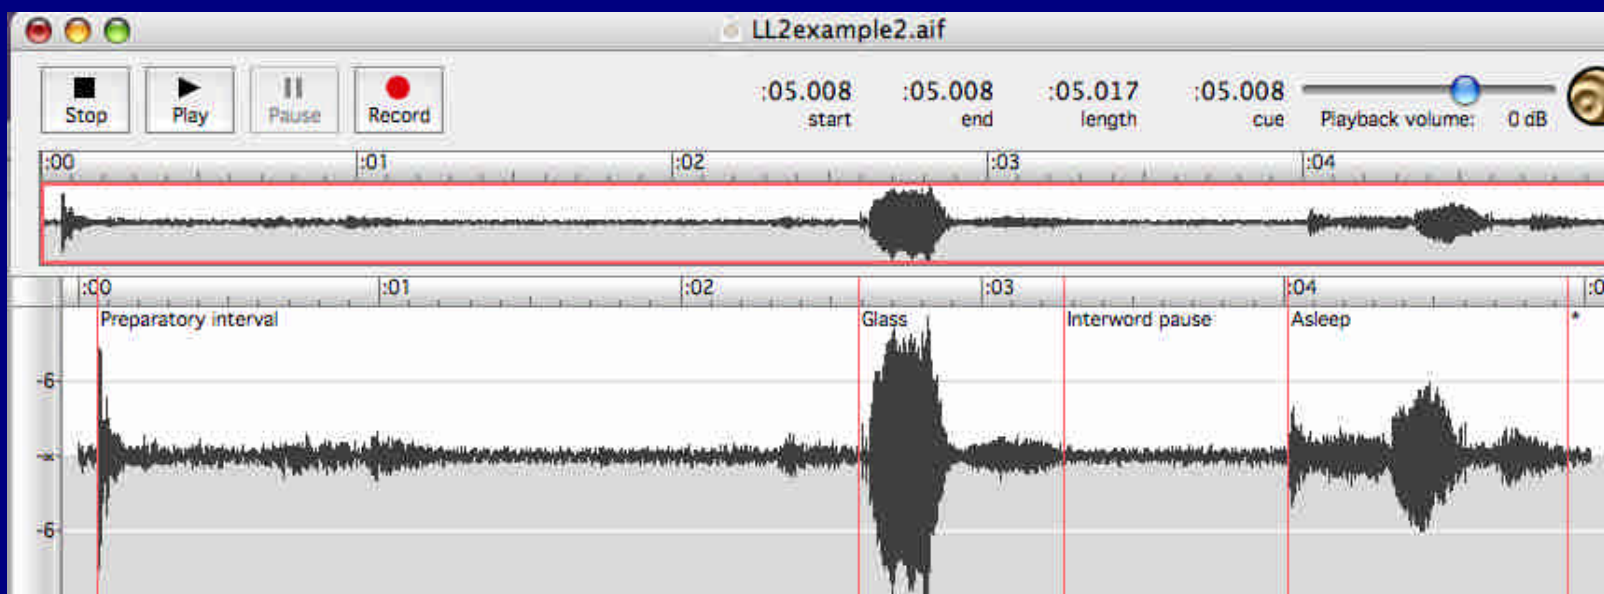

- As sequence length stays constant, one can ask various questions about memory, for example:
- Does each sequence item contribute to the predictive outcome of working memory? ✓
- Does the duration of individual processing events in the sequence matter for overall performance? ✓
- Is recall affected by the build up of proactive interference (PI) using items from repeated categories? ✓

Unpacking processing speed as a construct

- Arguments so far
 - Processing speed can be a useful global cognitive parameter
 - Yet processing speed can play different roles in explaining children's scholastic skills and development
 - The relationship between speed and span is potentially subtle and variable
 - There is merit in weaving processing time into the very fabric of memory measurements
- Processing speed can mean different things depending on the point of interest in the task...

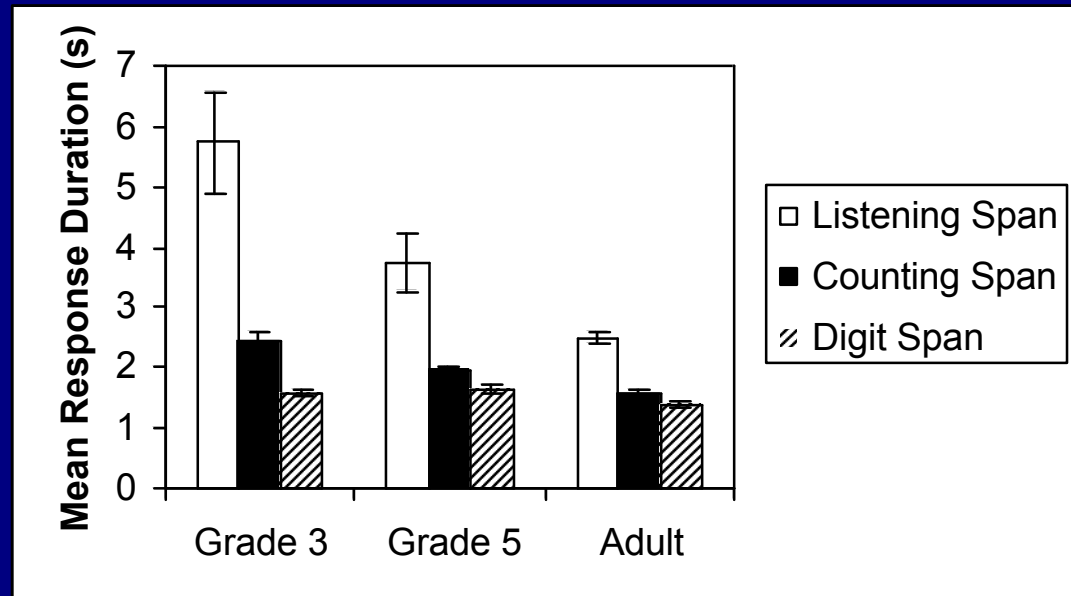

Example of reading span trial

- Recall isn't instantaneous
- Recall can be segmented into separate, contiguous elements
 - The gap before recall actually starts
 - The sequence words
 - The interword pauses

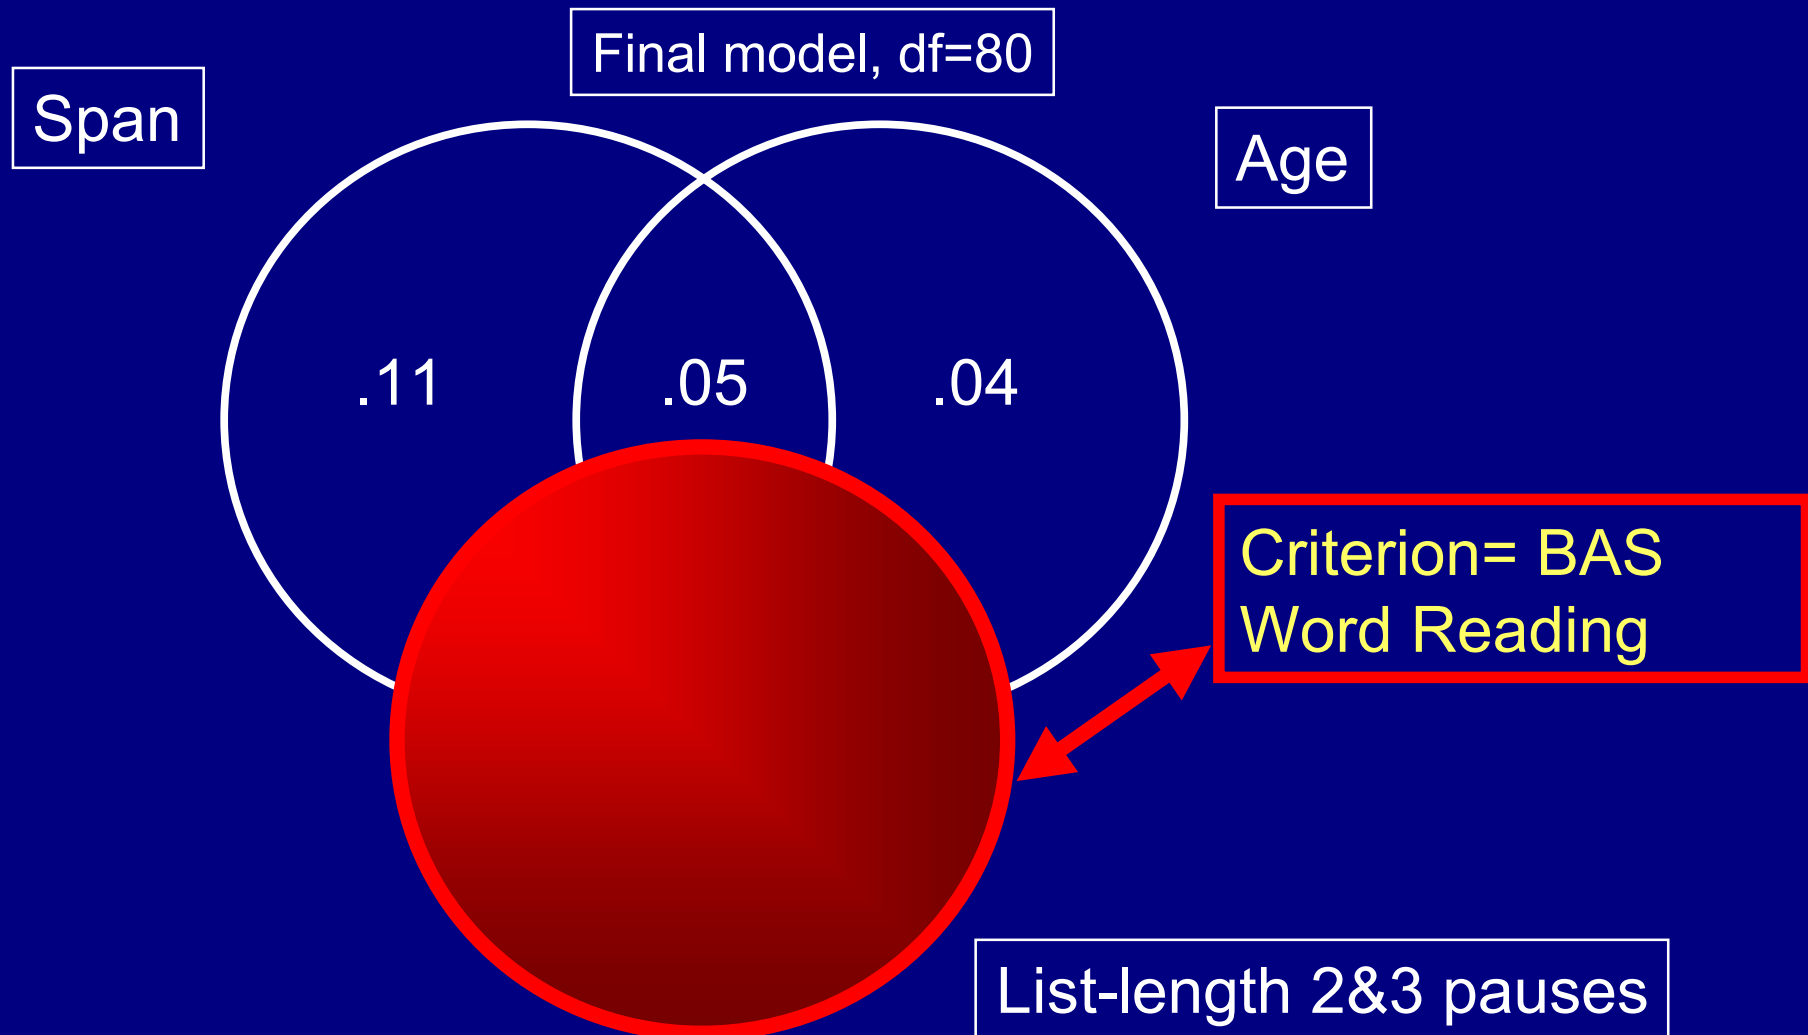

Recall timing in WM: data and theory

- Cowan, Towse, Hamilton, Saults, Elliott, Lacey, Moreno & Hitch (2003)
 - Length of recall episodes in reading span
 - Differences across tasks

Individual differences in recall timing

(re-analysed data from Towse, Cowan, Horton & Whytock, *Developmental Psychology*, 2008)

Macro-level variables underlying working memory capacity

- Processing speed

Macro-level variables underlying working memory capacity

- Processing speed
- Memory strength

Recall reconstruction hypothesis

(Towse, Cowan, Hitch, & Horton, *Experimental Psychology*, in press)

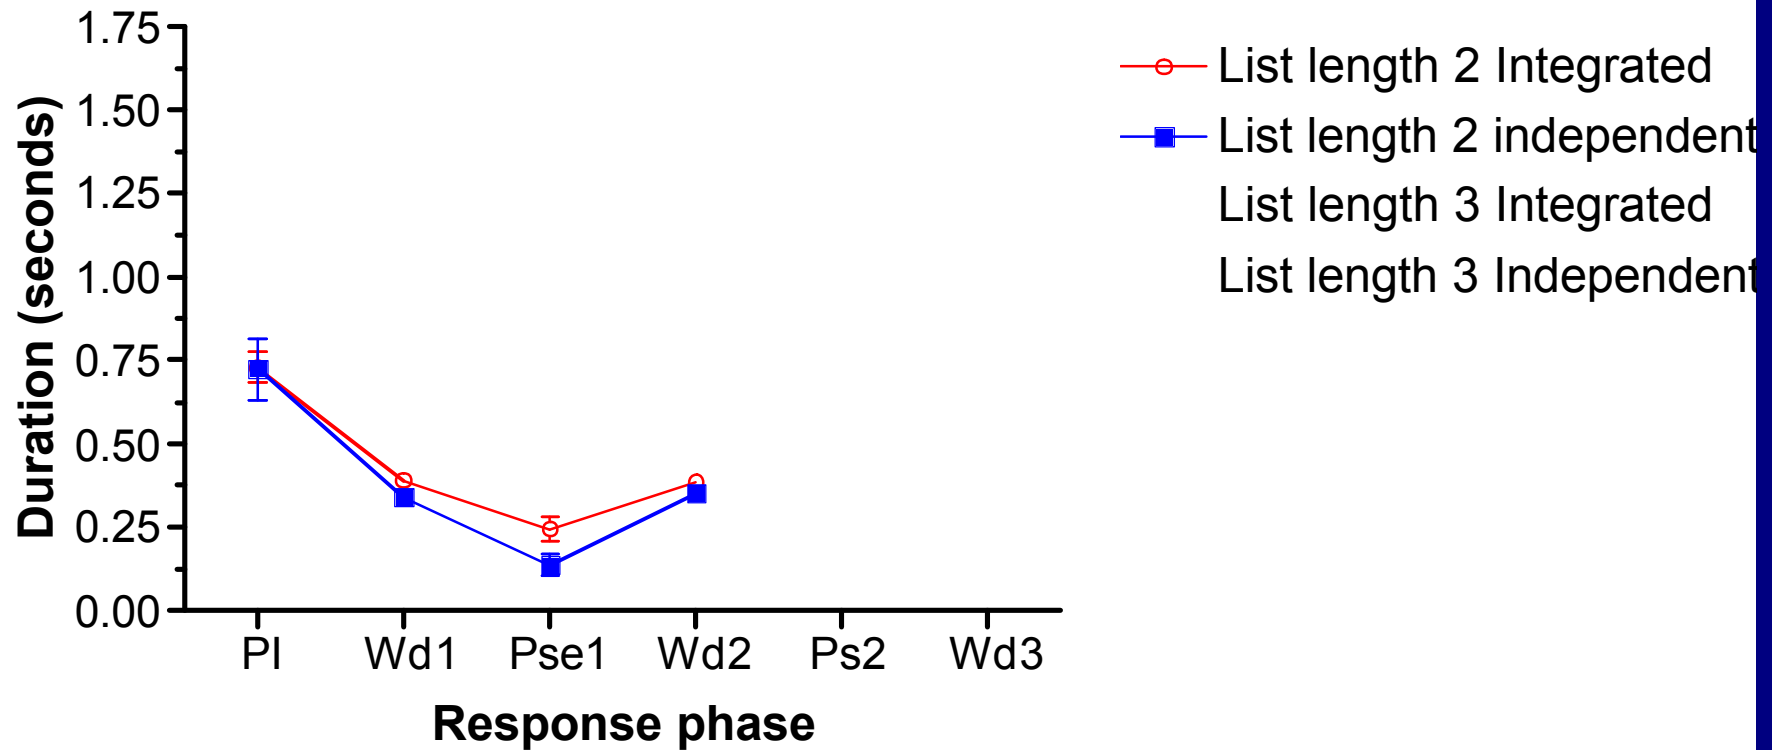

- Previous work shows that there are long pauses in reading span recall.
- The recall reconstruction hypothesis suggests some reasons why:
- *Participants may arrive at recall with several representations, including some from processing*
- *The output sequence is not always fully formed at the onset of a recall cue. The items themselves may not be complete*
- *Thus recall is not just a retrieval act, but a constructive one too*

Recall reconstruction hypothesis

(Towse, Cowan, Hitch, & Horton, *Experimental Psychology*, in press)

- Four experiments with broadly consistent outcomes
- Experiment 1:
- Recall span task administered to 24 adults
 - Read a sentence and remember the completion word
 - The rocket went into outer space. [space]
 - Referred to as the integrated condition
 - Read a sentence and remember an unconnected word that follows
 - The rocket went into outer space. [bridge]
 - Referred to as the independent condition

The profile of recall timing

The profile of recall timing

Developmental data relevant to recall reconstruction

- Towse, Hitch, Horton & Harvey (unpublished)
- N=108 children, ages 7, 9, and 11 years

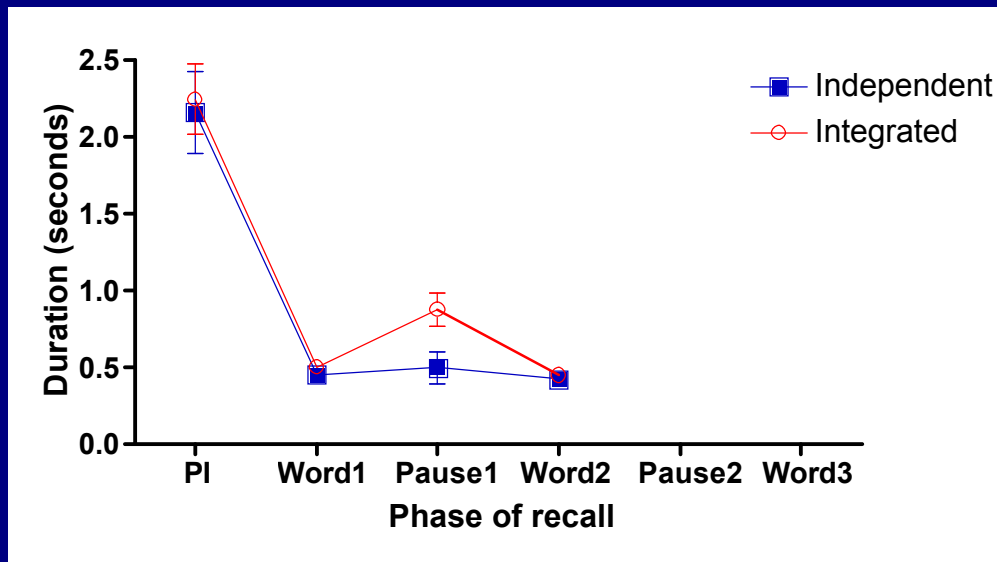

Age: $F(2, 101)=11.1, p<.001, h_p^2=.180$

Task: $F(1, 101)=28.2, p<.001, h_p^2=.218$

Interaction, $F(2,98)=1.61, h_p^2=.031$

Recall timing among children

The recall reconstruction hypothesis

- With integrated sentences, participants can draw upon sentence information for recall.
 - This facilitates recall accuracy
 - This is responsible for longer pauses in recall
 - Processing time dissociates at recall
- As a corollary...
 - Do some sentences scaffold recall better than other sentences in the integrated condition?

Recall reconstruction - sentence variance

- For every sentence/memorandum presentation, recorded whether subsequent recall was correct or not
- One can build up a profile of recall proportions for each of 88 sentences across all 54 participants
 - (ie item rather than subject analysis)

Why this won't work...

- Most recall variance will be attributable to
 - Sequence length
 - Serial position
 - Processing speed
 - Proactive interference
 - Specific intra-list combinations
 - Transient factors (e.g. distraction)
 - Etc.
- The sentence corpus was not developed to investigate variance in memorability
- Each child is presented with only a subset of the corpus, decreasing power
- The logic of reconstructive processes doesn't necessitate meaningful variance in sentence memorability

Recall reconstruction - sentence variance

- Some sentences were followed by correct recall more often than others
 - Some sentences with correct recall $>.9$
 - Some sentences with correct recall $<.4$
- But is this just random variance?

Recall reconstruction - sentence variance

- Carry out the same sentence analysis procedure on dataset reported in Towse et al. (2008) with integrated sentence type
 - Use ascending sequence length administration
 - Use first session data
 - Sequence length 2, 3, 4, & 5 where available.
- Different children, non-identical ages and non-identical procedure
 - Yet, recall proportions for the 88 sentences correlated in these two datasets, $r=.21$
- Despite all the reasons for the analysis to not work, there is consistency!

Recall reconstruction - sentence variance

- So consistency or reliability *has* been established in “recallability” of integrated material
- We have argued that recall reconstruction isn’t possible -in the same way- in the independent condition because the sentence/memorandum combination is different.
- Therefore, what happens to the recall proportions among the 54 children in the independent condition?
 - No correlation with the integrated condition, $r=.04$

		Towse et al. 08	Independent	Words
Weak recall	.397	.564	.456	.489
Strong recall	.897	.672	.516	.528

Recall reconstruction - Conclusions and implications

- Convergent evidence for reconstructive processes in complex span configurations
- Complex spans are not (just) dual task paradigms
- Macro-level, individual difference analysis (demonstrating recall pauses are predictive of span and ability) can be unpacked and complemented with micro-level experiments and item-level analysis.

Macro-level variables underlying working memory capacity

- Processing speed
- Memory strength

The graded nature of recall representations:

Towse, Hitch, Hamilton & Pirrie (in press)

- We tend to envisage that a memory is either available or inaccessible

Bridge

or

But should we
think about it as

Bridge

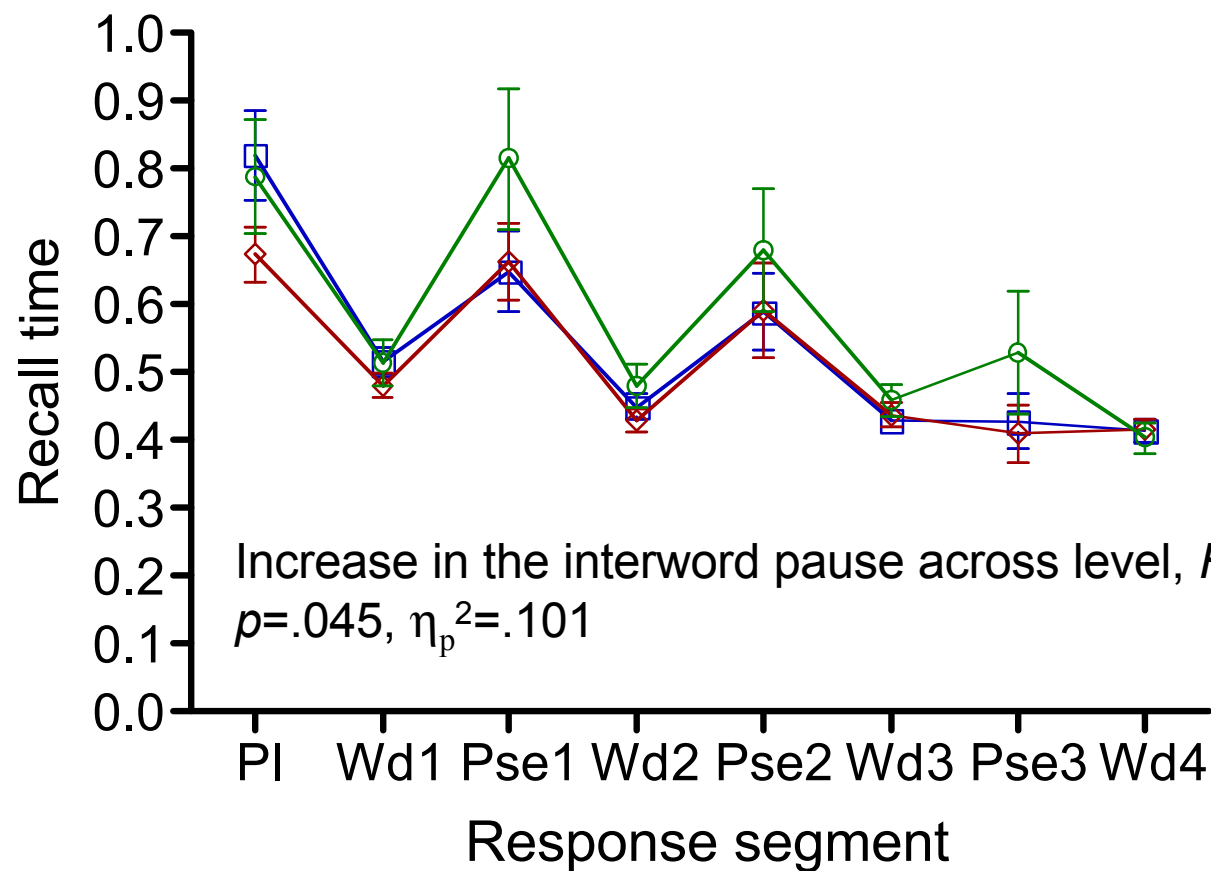

ie, graded in nature (Munakata, Morton & O'Reilly, 2007)

The graded nature of recall representations:

Towse, Hitch, Hamilton & Pirrie (in press)

- Investigating the demands in producing the correct answer
 - In the period task, the sequence length remains constant
 - But the retention characteristics do not
- Analysis of correct recall from 47 8-year-olds given a 4-event operation period task
 - Began with sums such as “ $6 + 0 =$ ”
 - Later given sums such as “ $5 + 1 =$ ”
 - And still later sums such as “ $4 + 1 + 1 =$ ”

Stretching the endurance of memory

Macro-level variables underlying working memory capacity

- Processing speed
- Memory strength

Macro-level variables underlying working memory capacity

- Processing speed
- Memory strength
- Executive attention

Unpacking executive attention

- Working memory span isn't just a primary task / secondary task environment
- Complex span paradigms can incorporate emergent properties (Towse & Houston-Price, 2001)
- Task decomposition can help refine what these emergent properties are
 - Bayliss, Jarrold, Gunn & Baddeley (2003)
 - Jarrold & Bayliss (2007)
- Once again, there's more to the dimension than initially meets the eye

Conclusions

- The value of convergent operations in working memory research
 - Macro and micro-level approaches
 - Potentially complementary perspectives from adults and children
- The richness of the working memory construct
 - We can go beyond simple, global, explanations
- The importance of understanding developmental mechanisms.

Metaphors for memory?

- The Suitcase metaphor
 - Size limits functionality
 - Some have bigger suitcases than others.
 - More items can be packed into a suitcase when the items are small.
 - Inefficient packing means that fewer items fit in the suitcase.
- One ought to measure suitcase size.
- The vacuum flask metaphor
 - Memories are perishable.
 - An important characteristic is how well memory traces are insulated against loss.
 - ...And how long they are left to degrade.
 - Size is not the (only) important dimension.
- One ought to measure endurance.

Comparison of tasks

Recall timing for different four-item memory tasks
